

OUTBOARD MOTOR SUPPORT DEVICE

BACKGROUND OF THE INVENTION

The invention pertains to supporting an outboard motor when it is mounted to a boat and placed in an up position. More particularly, it pertains to an outboard motor support device.

Fishing is one of the most popular recreational activities in North America. There are over 30 million anglers in the United States.

Over the past 25 years, there have been significant advances in fishing techniques and equipment. Magazines devoted to fishing in general, and even to specific species of fish have become popular and successful. Television programs about fishing and demonstrating fishing techniques and equipment are seen weekly. Sports and outdoor shows and expositions typically feature seminars by leading professional anglers; and video tapes demonstrating fishing techniques are proved to be popular.

Professional tournament fishing has steadily grown in popularity over the past two decades. Professional bass tournaments featuring large purses are conducted throughout the United States and are the subject of regular television programs. More recently, professional walleye tournaments have seen a similar rise in popularity.

Tournament fishing has led to many improvements in fishing techniques and technology as the professional anglers are constantly seeking to obtain a winning edge over competitors. In tournament walleye fishing, there has been a continuing trend toward larger boats with larger outboard motors. Where a 16 foot boat with a 40 or 50 horsepower tiller-controlled outboard motor was commonplace 10 years ago, tournament walleye fishing boats now are typically about 18 to 20 feet in length with an outboard motor in the range of 150 to 225 horsepower. These large boats and motors are needed to travel long distances on large bodies of water, since most professional walleye tournaments plays on large bodies of water in the Northern United States or Canada, such as the Great Lakes, the Mississippi River, the Missouri River, Lake Winnebago in Wisconsin, and Mille Lacs and Lake of the Woods in Minnesota.

A tournament walleye fishing boat is typically equipped with two other motors in addition to the main outboard motor: a bow mounted electric trolling motor and an auxiliary or "kicker" outboard motor mounted on the transom alongside the main outboard.

The electric trolling motor is used for precise boat positioning and movement. The electric trolling motor is quiet, which can be an advantage in shallow water. On the other hand, electric trolling motors have less thrust than either the main outboard or the kicker.

The kicker motor has become popular as trolling has become a widely used and very effective way of catching walleyes. The kicker motor is generally less than 20 horsepower, with 9.9 horsepower being the most common outboard motor used as a kicker. These smaller outboard motors were originally designed for smaller fishing boats, rather than as an auxiliary motor for a much larger boat.

The kicker motor can be used in a forward direction to troll at precise slow speeds (typically less than 3 miles per hour and in some cases less than 1 mile per hour). The kicker motor can also be used to "back troll", a technique in which the kicker motor is driven in reverse. This results in the boat moving very slowly in a reverse direction, or simply holding its place against current or waves in order to allow the angler to maintain a position over a particular underwater structure.

The increasing use of kicker motors, however, has lead to problems. When the boat is being driven at high speed from one location to another, the kicker motor must be tilted in its up position so that the lower unit of the kicker motor is out of the water. This avoids damage to the kicker motor, and also prevents the associated drag which would otherwise occur. However, when the boat is traveling at higher speeds, the pounding and bouncing of the boat across the water creates a stress on the bracket of the kicker motor, which can cause the bracket to break. This is especially true when the boat is running through swells. As the boat comes down hard from the top of a swell, the kicker motor's lower unit is snapped up pointing almost straight out from the transom of the boat. Then, when the boat bottoms out, the lower unit smashes down placing an extraordinary amount of force or stress on the bracket. These forces and stresses have been known to break the bracket which secures the kicker motor to the transom, and in some cases they have even broken a portion of the transom off of the boat where the bracket of the kicker is secured.

Designers have attempted to re-engineer the bracket to increase its strength. However, these efforts have been unsuccessful in overcoming the stresses associated with boats running through swells. Thus, there exists no known device to adequately support and secure a kicker motor in an up position while traveling over water at higher speeds.

SUMMARY OF THE INVENTION

The invention is a device and method to support and secure an outboard motor to a transom of a boat. The device comprises a tie down bracket, a support and a tie down strap. The tie down bracket is secured to the transom of the boat while the support is rotatably mounted to the motor. The support is mounted such that when the motor is in an up position the support can rotate about its mounting point to contact and support the motor. The tie down strap is then passed behind the motor and is secured to the tie down bracket. The motor is then secured in the up position between the support and the tie down strap which displaces a portion of the stress that would otherwise be placed on the mounting bracket of the motor and prevents the generation of forces or stresses by preventing movement of the motor while the boat is traveling at higher speeds or through semi-rough water from another power source.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a top view of a boat utilizing an outboard motor support device to secure and support an auxiliary motor.

FIG. 2 is a fragmentary view of a preferred embodiment of the invention.

FIG. 3 is a perspective starboard quarter view of a boat using a preferred embodiment of the invention with an outboard motor in an up position.

FIG. 4 is a perspective starboard quarter view of a boat having an outboard motor which is supported and secured in the up position by a preferred embodiment of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

In FIG. 1, a top view of boat 10 is shown. Boat 10 has a bow 12, a starboard side 14, a port side 16, a starboard quarter 18 and a port quarter 20. The boat 10 is powered by main outboard motor 22 and includes auxiliary outboard or "kicker" motor 24. The main outboard motor 22 and the kicker motor 24 are secured to a transom 26 of the boat 10. Electric trolling motor 28 is mounted on bow 12.

The support 54 includes cradle 64. V-frame 66, cross-bar 68, a pair of handles 70, lanyard 72 and a pair of sleeves 74. Cradle 64 is secured to the apex of V-frame 66. Cross-bar 68 is placed across V-frame 66 to add structural support to support 54. Cross-bar 68 extends beyond V-frame 66 to create handles 70 for support 54. Lanyard 72 has loops located at each end that slip over sleeves 74 to secure

Outboard motor support device 50 does not allow kicker motor 24 to bounce up and down or tilt further forward and

slam down to its up position when boat 10 travels at a high rate of speed or through rough waters or swells. Rather, kicker motor 24 is maintained in an up position which prevents the generation of the stresses and forces associated with kicker motor 24 bouncing up and down and thus avoids damage to either mounting bracket of kicker motor 24 or to transom 26 of boat 10.

Outboard motor support device 50 is simple in construction and easy to install. Most importantly, it is easy and quick to use.

Although the present invention has been described with reference to preferred embodiments, workers skilled in the art will recognize that changes may be made in form and detail without departing from the spirit and scope of the invention. For example, the support could have a different configuration than a V-frame or be mounted to a different location on the motor or the boat. Additionally, the tie down strap could be secured to the tie down bracket with another means, or only one end of the strap could be secured to the tie down bracket with the belt passing through a ring located at the other end of the belt to create a loop within which the motor would be captured.

What is claimed is:

1. An outboard motor support device for securing an outboard motor to a transom of a boat, the device comprising:

- a tie down bracket placed between a trim adjustment rack of the motor and the transom of the boat;
- a support rotatably mounted with respect to the motor such that when the motor is in an up position the support can rotate about its mounting point to contact and support the motor; and
- a tie down strap which passes behind the motor and is secured to the tie down bracket.

2. The device of claim 1, wherein the tie down bracket has a base plate which is secured adjacent to the transom by compression directed from the trim adjustment rack toward the transom and a pair of tabs that extend perpendicular to the base plate with the pair of tabs each having a hole.

3. The device of claim 1, wherein the tie down strap is adjustable in length and has a pair of ends that are secured to the tie down bracket on opposite sides of the motor.

4. The tie down strap of claim 3, wherein a hook is secured at each end of the tie down strap for securing the tie down strap to the tie down bracket through the holes on the pair of tabs.

5. The device of claim 1, wherein the support has a cradle which receives and secures the drive shaft housing of the motor.

6. The device of claim 5, wherein the support comprises a V-frame with a cross bar such that the opening of the V-frame mounts to the trim adjustment rack of the motor.

7. The device of claim 6, wherein the cross bar extends beyond the V-frame to form a pair of handles on either side of the V-frame.

8. The device of claim 1, wherein a lanyard is connected between the motor and the support to raise the support when the motor is raised to an up position.

9. The device of claim 1, wherein the support is rotatably mounted such that the support is positioned between the motor and the transom when the motor is in a down position.

10. The device of claim 9, and further including:
means connected between the support and the motor for rotating the support upward when the motor is tilted from the down position to the up position.

11. The device of claim 10, wherein the support includes a handle.

12. The device of claim 1, wherein the tie down bracket has a base plate which is mounted to the transom by bolts which mount the motor to the transom by passing through the trim adjustment rack of the motor and the base plate of the tie down bracket, the tie down bracket also including a pair of tabs that extend perpendicular to the base plate with the pair of tabs each having a hole.

13. An outboard motor support device for securing an outboard motor to a transom of a boat, the device comprising:

- a tie down bracket having a base which is secured to the transom and a first and a second tab which extend from the base oppositely facing each other, wherein the first and the second tabs each have a hole;

- a support formed in a V-frame having a cross bar and a cradle, wherein the opening of the V-frame is mounted in relation to the motor such that when the motor is in an up position the support can rotate about its mounting point and the cradle located at the apex of the V-frame receives and supports the motor along the drive shaft housing of the motor; and

- a tie down strap of adjustable length having a pair of hooks secured to its ends, wherein one of the hooks is secured in each one of the holes in the tabs and the tie down strap passes behind the drive shaft housing of the motor.

14. The device of claim 13, wherein the cross bar extends beyond the V-frame to form a pair of handles for the support on either side of the V-frame.

15. The device of claim 14, wherein the tie down strap passes beneath the handles of the support.

16. The device of claim 13, wherein a lanyard cable is connected between the motor and the support to raise the support when the motor is tilted to an up position.

17. A method for securing a motor to a transom of a boat, the method comprising:

- sliding a tie down bracket of an outboard motor support device between a transom of the boat and a trim adjustment rack of the motor;

- mounting the motor to the transom of the boat which compresses and secures the tie down bracket between the trim adjustment rack of the motor and the transom of the boat;

- tilting the motor to an up position;

- rotating a support of the motor support device which has a frame pivotally mounted with respect to the motor and which has a cradle, such that the cradle receives and supports the motor along a drive shaft housing of the motor; and

- securing a tie down strap of the motor support device to the tie down bracket such that the tie down strap passes behind the drive shaft housing of the motor and secures the motor in place between the cradle of the support and the tie down strap.

18. An outboard motor support device for securing an outboard motor to a transom of a boat, the device comprising:

- a tie down bracket;

- a support having a V-frame with a cradle at its apex which is rotatably mounted with respect to the motor such that when the motor is in an up position the support can rotate about its mounting point to contact and support the motor in the cradle; and

- a tie down strap which passes behind the motor and is secured to the tie down bracket.

19. The device of claim 18, wherein the tie down bracket has a base plate which is secured between the transom of the boat and a trim adjustment rack of the motor, the tie down bracket further including a pair of tabs that extend perpendicular to the base plate with the pair of tabs each having a hole.

20. The device of claim 18, wherein the tie down strap is adjustable in length and has a pair of ends that are secured to the tie down bracket on opposite sides of the motor.

21. The tie down strap of claim 20, wherein a hook is secured at each end of the tie down strap for securing the tie down strap to the tie down bracket.

22. The device of claim 18, wherein the cradle receives and secures the motor along a drive shaft housing of the motor.

23. The device of claim 22, wherein the V-frame opening of the support mounts to a trim adjustment rack of the motor.

24. The device of claim 22, wherein the V-frame has a cross bar which extends beyond the V-frame to form a pair of handles on either side of the V-frame.

25. The device of claim 18, wherein a lanyard is connected between the motor and the support to raise the support when the motor is raised to an up position.

26. The device of claim 18, wherein the support is rotatably mounted such that the support is positioned between the motor and the transom when the motor is in a down position and the axis of rotation for the support is along a plane parallel to the length of the boat.

27. The device of claim 26, and further including:

means connected between the support and the motor for rotating the support upward when the motor is tilted from the down position to the up position.

28. The device of claim 27 wherein the support includes a handle.
